ABSTRACT: In this paper we propose a new impact-parameter dependent CGC/saturation model. We introduce two new features in the model that make it consistent with what we know theoretically about the deep inelastic scattering. They are: the use of the exact form of the solution to the non-linear (BK) equation, whereas in all previous attempts only the form of $r^2 Q_s^2$ dependence, has been taken into account; and the large impact parameter dependence, through the b -dependence of the saturation momentum which reproduce the correct behaviour of the amplitude at large impact parameters b ($A \propto \exp(-\mu b)$) as well as at large momentum transferred Q_T (A decreases as a power of Q_T as it follows from perturbative QCD). These improvement compared to all previous attempts to build such models, allows us to claim, that the experimental data are in accord with the prediction of CGC/saturation approach while previously, based on similar models, we could only conclude that the DIS data, perhaps, can be described by introducing the shadowing corrections at small photon virtualities.

1 Introduction.

In this paper we continue our attempts to find an approach, based on Color Glass Condensate/saturation effective theory for high energy QCD (see Ref.[1] for the review), which will satisfy the following requirements: it is simple but stems from the solution of the CGC/saturation equations. In other words, we would like to reduce the *ad hoc* or/and phenomenological ingredients to the minimum. We believe that the comparison of our model with a variety of experimental data will allow us to demonstrate how the collective phenomena, that are incorporated in the CGC/saturation approach, are important for understanding scattering processes at high energies.

For comparison with experimental data, we choose the deep inelastic processes for which we have the CGC/saturation equations of Ref.[2] in a simple form of non-linear Balitsky-Kovchegov equation [3]. In addition to the simplicity of the theoretical interpretation of the deep inelastic structure function F_2 , these processes have been measured to high accuracy [4, 5], fitting to this observable allows us to determine all phenomenological parameters that are introduced in our model. However, the theoretical interpretation of this observable should also include the contribution of the colorless dipoles of large sizes, which require a non-perturbative description in the framework of QCD. In practice this means that we are not able to apply our approach to low Q^2 , where Q is the photon virtuality. It is advantageous to compare F_L with the data as the main contribution to this structure function, stems from dipoles of size $1/Q$. However, only we have scant data [6, 7] for F_L .

After determining the values of all phenomenological parameters of our approach from comparing to the data on F_2 , we calculate and compare with the experimental data on open charm, and J/Ψ meson diffractive production data [8–11]. These data can be described within our theory with the same accuracy as F_2 , as the wave function of J/Ψ meson is known. However, other sources of uncertainty such as the influence of the real part of the amplitude and/or the corrections that stem from the skewedness effect, due to the fact that the gluons attached to the $q\bar{q}$ can carry different light-cone fractions x and x' of proton, have to be taken into account. They lead to uncertainties which are not under full theoretical control. The same remarks can be made regarding the virtual Compton reaction ($\gamma^* + p \rightarrow \gamma + p$) [12] for which the wave function is known to even better accuracy than for J/Ψ production.

From the theoretical point of view, the description of the diffractive production of ϕ and ρ resonances [13] is less reliable, since we do not have a theoretical approach for the wave functions of these mesons, this in addition to all other uncertainties.

The main goal of comparing with experimental data, is to show that the CGC/saturation approach is able to describe all these processes. This paper is neither the first nor the last effort to build such a model based on the equations of CGC/saturation approach. Numerous attempts have been undertaken over the past two decades (see Refs.[14–33]) to build such models. Therefore, we clarify, in the introduction, the aspects of our model which are different.

First of all, it is necessary to construct a model, since the CGC/saturation equations cannot reproduce the correct behavior of the scattering amplitude at large impact parameters (see Ref.[34, 35]). Such failure leads, at least, to two conclusions: first, we cannot trust the solution of the CGC/saturation equations, and second, in attempting to describe experimental data we are doomed to build models to introduce the main features of the CGC/saturation approach.

We introduce the non-perturbative impact parameter behavior in the saturation moment, accordingly to the spirit of geometric scaling behavior of the scattering amplitude[36] and according to the semi-classical solution to the CGC/saturation equations [16]. Similar assumptions for the non-perturbative b -behavior of the scattering amplitude, is typical most models on the market (see Refs.[21–25, 28, 33]) and we refer only to the behavior at large b , of the saturation scale $Q_s(x, b)$. We introduce $Q_s(x, b) \xrightarrow{b \gg 1/\mu} \exp(-\mu b)$ while in all other models $Q_s(x, b) \xrightarrow{b \gg 1/\mu} \exp(-\mu^2 b^2)$. It should be stressed that the exponential decrease at

large b , is in accord the Froissart theorem [37]. We would like to emphasize that the b dependence in our model reproduces the perturbative QCD prediction for the large values of the momentum transferred (Q_T) leading to power-like behaviour of the scattering amplitude at large Q_T , which cannot be reproduced for the Gaussian b distribution in other models.

The main difference stems from the way we find the behavior of the dipole-nucleon scattering amplitude in the saturation region. In general, we follow the procedure suggested in Ref.[18]: we assume the geometric scaling behavior of the amplitude in the saturation region, and match the asymptotic behavior [38] deep inside the saturation region, with the behavior of this amplitude in the vicinity of the saturation scale [1, 39, 41]. We also take into account, not only the correct behavior of the scattering amplitude inside the saturation region (see Ref.[38]): viz. $N \propto \exp(-Az^2)$ with $z = \ln(r^2 Q_s^2)$ where r is the size of the dipole and Q_s is the saturation momentum, but the correct value of the coefficient A [38] and we specify the procedure of matching at $z = 0$. The procedure will be described below, and it is based on Ref.[42], to which we refer the reader for all details of this approach.

The natural question arises whether we introduce only slight, cosmetic changes to the models of Refs.[21–25, 28, 33] or the changes are principal in nature. We introduced in the model all theoretical information about the deep inelastic scattering, as, we believe, should be done in all phenomenological models, since the available experimental data are not sufficient to allow us to differentiate between theoretically correct and theoretically insufficient (or even wrong) approaches. It is enough to give an example of the deep inelastic scattering which can be described without any shadowing corrections (e.g. Ref.[40]). Therefore, we need only demonstrate that the theoretical changes that we introduce, are large enough to influence the description of the experimental data. This is the case since the correct b -behaviour leads to the $\ln^2(1/x)$ increase of the deep inelastic structure function F_2 , while the correct behaviour at large z determines the coefficient in front of $\ln(1/x)$ in F_2 . Our numerical estimates show that both factors are essential in the description of the HERA data, and become even more significant at higher energies.

As will be seen from the body of the paper, our model provides a good description of the experimental data. The fact that this description does not appear better than in the other insufficient models on the market, allows us to claim that the CGC/saturation approach does not contradict the available experimental data. On the other hand we learned only that shadowing corrections are, perhaps, needed to describe the experimental data from comparison with the experiment all models of Refs.[14–33].

2 Theoretical input

2.1 General formula

The general formula for deep inelastic processes takes the form (see Fig. 1 and Ref. [1] for the review and references therein)

$$N(Q, Y; b) = \int \frac{d^2 r}{4\pi} \int_0^1 dz \Psi_{\gamma^*}(Q, r, z) N(r, Y; b) \Psi_V^*(r, z) \quad (2.1)$$

where $Y = \ln(1/x_{Bj})$ and x_{Bj} is the Bjorken x . z is the fraction of energy carried by quark. Q is the photon virtuality. b is the impact parameter of the scattering amplitude.

Eq. (2.1) splits the calculation of the scattering amplitude into two stages: calculation of the wave functions, and estimates of the dipole scattering amplitude.

Figure 1. The graphic representation of Eq. (2.1) for the scattering amplitude. $Y = \ln(1/x_{Bj})$ and r is the size of the interacting dipole. z is the fraction of energy that is carried by one quark. b is the impact parameter of the scattering amplitude

2.2 Dipole-nucleon scattering amplitude

We follow the general plan of Ref.[18], searching for a solution to the CGC/saturation equation, by matching the solution in the vicinity of the saturation scale, with the solution deep inside the saturation domain. In both these regions we have analytical solutions.

2.2.1 Vicinity of the saturation scale

Dipoles of sizes r are such, that $r^2 Q_s^2(Y, b) \rightarrow 1$ the scattering [1, 39, 41]

$$N(r, Y; b) = N_0 (r^2 Q_s^2(b))^{1-\gamma_{cr}} \quad (2.2)$$

where γ_{cr} is the solution of the equation

$$\frac{\chi(\gamma_{cr})}{1-\gamma_{cr}} = \left| \frac{d\chi(\gamma_{cr})}{d\gamma_{cr}} \right| \quad (2.3)$$

In Eq. (2.3) $\chi(\gamma)$ is the BFKL kernel that takes the form

$$\chi(\gamma) = 2\psi(1) - \psi(\gamma) - \psi(1-\gamma) \quad (2.4)$$

where $\psi(z)$ is the digamma function.

The scattering amplitude of Eq. (2.3) shows the geometric scaling behaviour [36]. In Ref. [39] it is shown that the first corrections due to a violation of the geometric scaling behavior can be taken into account by replacing $1 - \gamma_{cr}$ in Eq. (2.2) by the following expression

$$1 - \gamma_{cr} \rightarrow 1 - \gamma_{cr} - \frac{1}{2\kappa\lambda Y} \ln(r^2 Q_s^2(b)) \quad (2.5)$$

where $\lambda = \bar{\alpha}_S(\chi(\gamma_{cr})/(1-\gamma_{cr}))$ and $\kappa = \chi''(\gamma_{cr})/\chi'(\gamma_{cr})$.

2.2.2 Saturation region

The new ingredient in our model is the way we found the solution to the Balitsky-Kovchegov (BK) equation [3] in the saturation region where $r^2 Q_s^2(Y, b) > 1$. In this region the scattering amplitude demonstrates geometric scaling behavior, being a function of one variable

$$z = \ln(r^2 Q_s^2(Y, b)) = \ln(r^2 Q^2(Y = Y_0, b)) + \lambda(Y - Y_0) = \xi + \lambda(Y - Y_0) \quad (2.6)$$

since the saturation scale behaves as

$$Q_s^2(Y, b) = Q^2(Y = Y_0, b) e^{\lambda(Y - Y_0)} = Q^2(Y = Y_0, b) \left(\frac{x_0}{x}\right)^\lambda \quad (2.7)$$

where $Y = \ln(1/x)$, x is the Bjorken energy variable which is equal to $x = Q^2/s$ for deep inelastic scattering. Q is the photon virtuality and s is the energy squared for the process.

Deep in the saturation region ($z \gg 1, r^2 Q_s^2(Y, b) \gg 1$) the solution to the non-linear BK equation is known (see Ref.[38]). In Refs.[42] the next order correction to asymptotic behavior at large z has been calculated. In this paper we use the following expression taken from Ref.[42]

$$N^{z \gg 1}(z) = 1 - 2Ae^{-\mathcal{Z}} - \sqrt{2\lambda} A^2 \frac{1}{\sqrt{\mathcal{Z}}} e^{-2\mathcal{Z}} + \mathcal{O}(e^{-3\mathcal{Z}}) \quad (2.8)$$

$$\mathcal{Z} = \frac{\left(z - \frac{1}{2}A\sqrt{\lambda\pi/2} - 2\psi(1)\right)^2}{2\lambda}$$

where $\psi(x)$ is the digamma function (see Ref.[43] formula **8.360 - 8.367**).

The second term in Eq. (2.8) is the solution given in Ref.[38] in which the theoretically unknown constant A is introduced both as the coefficient in front and as correction to the argument. The third term is the next order correction at large z .

For $z > 0$ but $z \ll 1$, the solution to BK equation has been found in Ref.[42] and it takes the form

$$N^{0 < z \ll 1}(z) = -2 \frac{\lambda(1 - \gamma_{cr})^2 (N_0 - \lambda(1 - \gamma_{cr})) N_0 e^{-(1 - \gamma_{cr})z}}{(N_0 - (N_0 - \lambda(1 - \gamma_{cr})) e^{-(1 - \gamma_{cr})z})^2} \quad (2.9)$$

where N_0 is the value of the scattering amplitude at $z = 0$.

We match these two solution at $z = z_m$ where

$$N^{0 < z \ll 1}(z = z_m) = N^{z \gg 1}(z = z_m); \quad \frac{dN^{0 < z \ll 1}(z = z_m)}{dz_m} = \frac{dN^{z \gg 1}(z = z_m)}{dz_m}; \quad (2.10)$$

It has been demonstrated in Ref.[42] that we find $z_m \approx 1$.

2.2.3 Estimates for the parameters of the scattering amplitude

The entries in Eq. (2.2), Eq. (2.8) and Eq. (2.9) can be divided in two groups: parameters that can be evaluated in the leading $\log(1/x)$ approximation of perturbative QCD, and phenomenological parameters that can be found only by comparing with the experimental data. The value of γ_{cr} is determined by Eq. (2.3) and it is equal to 0.37. The energy dependence of the saturation scale is given by

$$\lambda = \bar{\alpha}_S \chi(\gamma_{cr}) / (1 - \gamma_{cr}). \quad (2.11)$$

In Eq. (2.5) $\kappa = \chi''(\gamma_{cr}) / \chi'(\gamma_{cr})$ in the leading order of perturbative QCD(LO). In our procedure of fitting we consider the value of λ as a parameter of the fit since we do not know the value of $\bar{\alpha}_S$ and the next-to-leading order corrections (NLO) in perturbative QCD change considerably the value of λ [41, 44] making it in 3-4 times less than the LO estimates. The value of λ is determined by the linear BFKL equation which is known in the NLO, and therefore, we consider the estimates of λ as reliable, which have to be taken into account in spite of uncertainties in the value. $\lambda \approx 0.2$ which we obtain from the fit is close to the NLO estimates.

In principle the value of N_0 can be calculated using the linear evolution equation with the initial conditions. However, it depends on the phenomenological parameters of this initial condition. We choose to use N_0 as the parameter of the fit.

The impact parameter dependence of the saturation scale as we have discussed, is the pure phenomenological input, which can only be estimated in non-perturbative QCD. For $Q_s(Y = Y_0, b)$ we use the following expression

$$Q_s^2(Y = Y_0, b) = m^2 S(b) = m^2 (m b K_1(m b))^{1/(1-\gamma_{cr})} \quad (2.12)$$

m must be determined from the fit. We differ from other models in that Eq. (2.12) leads to

$Q_s^2(Y = Y_0, b) \xrightarrow{mb \gg 1} \exp(-mb/(1 - \gamma_{cr}))$ providing the correct large b behavior of the scattering amplitude. In other models (see Refs.[21–25, 28, 33]) $Q_s^2(Y = Y_0, b) \propto \exp(-b^2/B)$.

2.3 Wave functions

The wave function in the master equation (see Eq. (2.1)) is the main source of theoretical uncertainties: even in the case of deep inelastic processes, we can trust the wave function of perturbative QCD only, at rather large values of $Q^2 \geq Q_0^2$ with $Q_0^2 \approx 0.7 \text{ GeV}^2$ (see Ref. [45]). The expression for $(\Psi^* \Psi)^{\gamma^*} \equiv \Psi_{\gamma^*}(Q, r, z) \Psi_{\gamma^*}(Q, r, z)$ is well known (see Ref.[1] and references therein)

$$(\Psi^* \Psi)_T^{\gamma^*} = \frac{2N_c}{\pi} \alpha_{\text{em}} \sum_f e_f^2 \{ [z^2 + (1-z)^2] \epsilon^2 K_1^2(\epsilon r) + m_f^2 K_0^2(\epsilon r) \}, \quad (2.13)$$

$$(\Psi^* \Psi)_L^{\gamma^*} = \frac{8N_c}{\pi} \alpha_{\text{em}} \sum_f e_f^2 Q^2 z^2 (1-z)^2 K_0^2(\epsilon r), \quad (2.14)$$

where $T(L)$ denotes the polarization of the photon and f is the flavours of the quarks. $\epsilon^2 = m_f^2 + Q^2 z(1-z)$.

In addition to the total DIS cross section, the wave function is known theoretically for deeply virtual Compton scattering (DVCS). For this process $(\Psi^*\Psi)^{DVCS} \equiv \Psi_\gamma(r, z) \Psi_{\gamma^*}(Q, r, z)$ is equal to

$$(\Psi_\gamma^*\Psi)_T^{DVCS} = \frac{2N_c}{\pi} \alpha_{\text{em}} \sum_f e_f^2 \{ [z^2 + (1-z)^2] \epsilon K_1(\epsilon r) m_f K_1(m_f r) + m_f^2 K_0(\epsilon r) K_0(m_f r) \}. \quad (2.15)$$

Since in DVCS the real photon is produced, so its polarization can be only transverse, as seen from Eq. (2.15).

For vector meson diffractive production, the wave functions are known only for the mesons that are constituted of heavy quarks. The most popular example is the J/ψ diffractive production, but we have to bear in mind, that the mass of the charm quark is not very large, and corrections can be essential. For all other mesons the confinement corrections are large and the form of the wave functions motivated by the heavy quark mesons, can be considered only as a pure phenomenological conjecture. We use the following form of the overlaps integrals $(\Psi_V^*\Psi)_{T,L} \equiv \Psi_{\gamma^*}(Q, r, z) \Psi_{T,L}^V(r, z)$ taking them from Ref.[22]

$$(\Psi_V^*\Psi)_T = \hat{e}_f e \frac{N_c}{\pi z(1-z)} \{ m_f^2 K_0(\epsilon r) \phi_T(r, z) - [z^2 + (1-z)^2] \epsilon K_1(\epsilon r) \partial_r \phi_T(r, z) \}, \quad (2.16)$$

$$(\Psi_V^*\Psi)_L = \hat{e}_f e \frac{N_c}{\pi} 2Qz(1-z) K_0(\epsilon r) \left[M_V \phi_L(r, z) + \frac{m_f^2 - \nabla_r^2}{M_V z(1-z)} \phi_L(r, z) \right], \quad (2.17)$$

$$\phi_{T,L}(r, z) = \mathcal{N}_{T,L} z(1-z) \exp \left(-\frac{m_f^2 \mathcal{R}^2}{8z(1-z)} - \frac{2z(1-z)r^2}{\mathcal{R}^2} + \frac{m_f^2 \mathcal{R}^2}{2} \right) \quad (2.18)$$

where the effective charge $\hat{e}_f = 2/3, 1/3$, or $1/\sqrt{2}$, for J/ψ , ϕ , or ρ mesons respectively. $m_f = 140 \text{ MeV}$ is used in all above equations and the values of $\mathcal{N}_{T,L}$ and $\mathcal{R}$ are taken from Table 2 in Ref. [19].

2.4 Other theoretical uncertainties

2.4.1 Real part of the scattering amplitude

The master equation (see Eq. (2.1)) is derived assuming that the scattering amplitude is purely imaginary. To account for the real part of the amplitude, we need to multiply the differential cross section calculated by using Eq. (2.1) by factor $1 + \rho^2$ where ρ is the ratio of real to imaginary parts of the scattering amplitude A . In principle, we can calculate the real part of the amplitude if we know the imaginary part using the dispersion relation. For large values of energy this calculation simplifies to

$$\rho = \frac{\pi}{2} \frac{d \ln(N)}{d \ln(1/x)} \quad (2.19)$$

for a more general formula for the amplitudes that show Regge-type behavior at high energies (see Ref.[46] and references therein)

$$\rho = \tan(\pi\beta/2), \quad \text{with} \quad \beta \equiv \frac{\partial \ln(N_{T,L}^{\gamma^* p \rightarrow Vp})}{\partial \ln(1/x)}. \quad (2.20)$$

2.4.2 Off diagonal contributions

For vector meson production or DVCS, we need to modify the main formula of Eq. (2.1), to account for the fact that the virtual photon, and the produced vector mesons carry different fractions x and x' of the proton's (light-cone) momentum. In the leading $\ln(1/x)$ limit, this imbalance (skewed effect) does not affect the scattering amplitude, but it has to be taken into account in the limit that $x' \ll x \ll 1$. To include the skewed effect we multiply the amplitude by the factor R_G given by [47]

$$R_g(\beta) = \frac{2^{2\beta+3}}{\sqrt{\pi}} \frac{\Gamma(\beta + 5/2)}{\Gamma(\beta + 4)} \quad (2.21)$$

where β is given by Eq. (2.20).

3 Fitting F_2 and values of the parameters

The most accurate experimental data available are on the deep inelastic structure function F_2 [4]. Our strategy is to determine all phenomenological parameters by fitting to these data. Other data we will use to illustrate that our model can be used as a simple and convenient tool in describing a variety of processes. As has been mentioned, we can trust our model in the restricted kinematic region, which we choose in the following way: $0.85 \text{ GeV}^2 \leq Q^2 \leq 60 \text{ GeV}^2$ and $x \leq 0.01$. The lower limit of Q^2 stems from non-perturbative correction to the wave function of the virtual photon, while the upper limit is originated from the restriction $x \leq 0.01$.

λ	N_0	$m \text{ (GeV)}$	$Q_0^2 \text{ (GeV}^2\text{)}$	$m_u \text{ (MeV)}$	$m_d \text{ (MeV)}$	$m_s \text{ (MeV)}$	$m_c \text{ (GeV)}$	$\chi^2/d.o.f.$
0.197	0.34	0.75	0.145	2.3	4.8	95	1.4	178/155 = 1.15
0.184	0.46	0.75	0.118	140	140	140	1.4	176/154 = 1.14

Table 1. Fitted parameters of the model. $Q_0^2 = m^2 x_0^\lambda$.

We have the following fitting parameters: λ for x -dependence of the saturation momentum, N_0 for the value of the scattering amplitude at $r^2 Q_s^2 = 1$, m for the impact dependence of the saturation scale and x_0 or $Q_0^2 = m^2 x_0^\lambda$ for the value of the saturation scale. Masses of the quark we do not regard as fitting parameters and consider two sets of these masses. In the first set we take the current masses (see the first row of Table 1) and we consider this as the most reliable fit based on the consistent theoretical approach. We also make a fit putting all masses of light quarks (second row of Table 1) to be equal to 140 MeV. We view this mass as a typical infra-red cutoff, which was used in the wave functions of the produced mesons ($m_f = 140 \text{ MeV}$ in Eq. (2.16) and Eq. (2.17)).

Table 1 gives the values of the fitting parameters and Fig. 2 demonstrates the quality of the fit.

One can see from the Table 1 that both sets of parameters give good descriptions of the experimental data and the values of the parameters are very close for both fits. The value of λ leads to very small value of the QCD coupling $\bar{\alpha}_S$ in Eq. (2.11), but, as we have discussed, the estimates in the NLO of perturbative

Figure 2. Our fit of F_2 with the values of parameters given by Table 1. The first set of parameters is shown in solid red curves while the second in blue dotted lines. The data is taken from Ref.[4].

QCD lead the value of λ [41, 44] which is much smaller than in Eq. (2.11) and which is close to the value that we obtain from the fit. The value of N_0 turns out to be small enough, to use our matching procedure. $Q_0^2 = m^2 x_0^\lambda$ looks reasonable and generates the values of the saturation momentum shown in Fig. 3.

The value of m is smaller than the typical mass in the electro-magnetic form factor of the proton, but we do not expect that it will be the same. The mass that we extract from our fit is close to the mass of ρ -meson. However, it should be noted that the decrease of Q_s^2 at large b is proportional to $\exp\left(-\frac{m}{1-\gamma_{cr}}b\right) = \exp(-1.2(GeV^{-1})b)$. On the other hand the behavior of amplitude with b differs from the saturation scale. In Fig. 4 one can see that both the saturation, and the violation of the geometric scaling behavior influence the resulting b -dependence of scattering amplitude. The saturation flattens

Figure 3. The value of the saturation momentum $Q_s^2(x, b)$ versus x at fixed b for the parameters given by Table 1.

the b -dependence at small values of b , while the large b behaviour shows a more rapid decrease than the b -dependence of the saturation scale (see Fig. 4).

Figure 4. The b -dependence of the scattering amplitude for the parameters given by Table 1. $S(b)$ is given by Eq. (2.12).

It should be stressed that in the framework of our parametrization of the b -dependence of the saturation momentum, the scattering amplitude decreases as $\exp(-mb)$ while in all other models on the market it has a Gaussian behavior: $\exp(-m^2 b^2)$.

Fig. 5 we present the comparison between our fit of F_2 with two sets of parameters at low values of Q . The set with large masses of quarks leads to a much better description illustrating the the non-perturbative corrections to the wave function of the virtual photon are essential at $Q^2 < 0.85 \text{ GeV}^2$.

Figure 5. The x -dependence of $F_2^{c\bar{c}}$ at small values of $Q^2 < 0.85 \text{ GeV}^2$ for the parameters given by Table 1. The red (upper) line corresponds to set 1 (upper row of Table 1) while the blue one (low) is the description with set 2. The data are taken from Ref.[6, 7].

4 Comparison with the experimental data

In this section we compare the predictions of our approach using the set of parameters shown in Table 1, with the experimental data.

$F_2^{c\bar{c}}$: The contribution of the $c\bar{c}$ pair to the deep inelastic structure function can be calculated with the same theoretical accuracy as the inclusive F_2 . In Fig. 6 we compare the HERA data on F_2^{cc} [5] with the theoretical predictions. One can see that the agreement is reasonable.

F_L : F_L can be calculated within the same accuracy as $F_2^{c\bar{c}}$, and the comparison with the scant data available [6, 7] is plotted in Fig. 7. Two sets produce the same quality of the descriptions since the values of Q are rather large.

Main formulae for cross sections of exclusive diffractive production:

First, we need first to calculate the scattering amplitude at fixed t which takes the following form [22]:

$$\mathcal{A}_{T,L}^{\gamma^* p \rightarrow V p}(x, Q, \Delta) = i \int d^2 \mathbf{r} \int_0^1 \frac{dz}{4\pi} \int d^2 \mathbf{b} (\Psi_V^* \Psi)_{T,L} e^{-i[\mathbf{b} - (1-z)\mathbf{r}] \cdot \Delta} N(r, Y; b) \quad (4.1)$$

where $|\Delta|^2 = -t$.

Figure 6. The x -dependence of $F_2^{c\bar{c}}$ at fixed values of Q^2 : $0.85 \leq Q^2 \leq 60 \text{ GeV}^2$ for the parameters given in Table 1. The data are taken from Ref. [5].

The elastic diffractive cross section is then given by

$$\frac{d\sigma_{T,L}^{\gamma^* p \rightarrow Vp}}{dt} = \frac{1}{16\pi} \left| \mathcal{A}_{T,L}^{\gamma^* p \rightarrow Vp} \right|^2 = \frac{1}{16\pi} \left| \int d^2 \mathbf{r} \int_0^1 \frac{dz}{4\pi} \int d^2 \mathbf{b} (\Psi_V^* \Psi)_{T,L} e^{-i[\mathbf{b} - (1-z)\mathbf{r}] \cdot \mathbf{\Delta}} N(r, Y; b) \right|^2. \quad (4.2)$$

If we restrict ourselves to measuring two integrated observables: $\sigma_{T,L}^{\gamma^* p \rightarrow Vp} = \int dt \frac{d\sigma_{T,L}^{\gamma^* p \rightarrow Vp}}{dt}$ and $B_D = \ln \left(\frac{d\sigma_{T,L}^{\gamma^* p \rightarrow Vp}}{dt} / \frac{d\sigma_{T,L}^{\gamma^* p \rightarrow Vp}}{dt} \Big|_{t=0} \right)$, Eq. (4.1) and Eq. (4.2) can be simplified.

Figure 7. The x -dependence of F_L at fixed values of Q^2 : $0.85 \leq Q^2 \leq 60 \text{ GeV}^2$ for the parameters given in Table 1. The red (blue) lines correspond to set 1 and set 2 fits. The data are taken from Ref. [7].

The formulae for them take the following form

$$\sigma^{\gamma^* p \rightarrow Vp} = \frac{1}{16\pi} \left(\int d^2 \mathbf{b} \right. \quad (4.3)$$

$$\left. \left\{ \int d^2 \mathbf{r} \int_0^1 \frac{dz}{4\pi} (\Psi_V^* \Psi)_{T,L} N(r, Y; b) \right\} \left\{ \int d^2 \mathbf{r}' \int_0^1 \frac{dz'}{4\pi} (\Psi_V^* \Psi)_{T,L} N(r', Y; \mathbf{b} - (1 - z') \mathbf{r}') \right\}^* \right);$$

$$\sigma^{\gamma^* p \rightarrow Vp} B_D = \frac{1}{16\pi} \left(\int d^2 \mathbf{b} d^2 \mathbf{r} d^2 \mathbf{r}' \int_0^1 \frac{dz}{4\pi} \int_0^1 \frac{dz'}{4\pi} \right. \quad (4.4)$$

$$\left. (4b^2 + (1 - z)^2 r^2 + (1 - z')^2 r'^2) \left\{ (\Psi_V^* \Psi)_{T,L} N(r, Y; b) \right\} \left\{ (\Psi_V^* \Psi)_{T,L} N(r', Y; \mathbf{b} - (1 - z) \mathbf{r}') \right\}^* \right).$$

Deeply virtual compton scattering(DVCS)

Deeply inelastic Compton scattering: $\gamma^* + p \rightarrow \gamma + p$, can be calculated to the same accuracy as all reactions that has been discussed, but it suffers from the errors due to the procedure for calculating both the real part of the amplitude and its skewness. Fig. 8 shows the comparison with the data, taken from Refs.[12]. One can see that the description of the cross sections are satisfactory, while the energy dependence of the slope turns out to be more complicated than in the experimental data.

Fig. 8-a

Fig. 8-b

Fig. 8-c

Figure 8. The energy (Fig. 8-a) and Q^2 (Fig. 8-b) dependence of the cross section for deep inelastic compton scattering. Fig. 8-c shows the energy dependence of the slope. The data are taken from [12]. The lines correspond to the set 1 of the parameters. The red color describe the H1 data while the blue one stand for ZEUS data.

Total cross sections for diffractive production of vector mesons $\sigma^{\gamma^* p \rightarrow V p}$ (see Eq. (4.3))

In Fig. 9 and Fig. 10 we compare our prediction with the experimental data [8–11] for productions of J/Ψ , ϕ and ρ -mesons.

We introduce the factor $(1 + \rho^2)R_G^2$ to account for the real part of the amplitude and for the skewness as has been discussed in section 2.4. One can see that agreement is good, and the heavier the produced meson, the better the agreement, as expected.

The slopes B_D : B_D are calculated using Eq. (4.4) and Fig. 11 shows the comparison with the experiment data taken from Refs. [8–11]. In Fig. 12 we plot the dependence of the slope on the energy W . We are able to describe the values and main regularities of the slope's behavior on Q^2 and W . Fig. 12 shows the the shrinkage of the diffraction peak is very mild.

5 Conclusions

In this paper we add to the many CGC/saturation models [14–33] two crucial ingredients: the correct solution to the non-linear (BK) equation [3] in the saturation region, and impact parameter distribution that leads to exponential decrease of the saturation momentum at large impact parameters and to power-

Fig. 11-a

like decrease at large transferred momentum that follows from perturbative QCD. We obtain the solution to the BK equation based on the ideas proposed in Ref.[18]: to match the analytical solution for the scattering

amplitude deep inside of the saturation domain [38] with the solution in the vicinity of the saturation momentum [39, 41]. The novel features of our approach is that we use the exact form of the solution to the BK equation (see section 2.2 and Refs.[38, 42]) but not the form of $r^2 Q_s^2$ dependence as have been assumed in all previous attempts. We introduce the large impact parameter dependence through the b -dependence of the saturation momentum. The difference between our and the other attempts consists in the assumption that $Q_s^2 \propto \exp(-mb)$ at large b , while in all other models the Gaussian behavior at large b $Q_s^2 \propto \exp(-m^2 b^2)$ is assumed. In the framework of our model, the exponential b dependence of Q_s^2 translates in the exponential decrease of the scattering amplitude at large b , satisfying the Froissart theorem [37].

Using four fitting parameters we obtain good overall agreement with the experimental data. Comparison with the experimental data we found two regularities. The first one is, the better we know theoretically the wave functions of the produced mesons, the better the agreement with experimental data. The second is the fact, that the energy dependence of the saturation momentum, is much milder than it is predicted by the BK equation in leading $\log(1/x)$ approximation of perturbative QCD. The last observation, we hope, will stimulate the search for the non-linear equation, in the next-to-leading order (NLO) of perturbative QCD. The first attempts to estimate the energy behavior of the saturation scale in NLO show that the value of λ significantly decreases (see Refs.[41, 44, 49, 50]).

We believe that the model presented here, will be a useful tool to estimate the CGC/saturation effects in the variety of exclusive reactions.

The model includes everything that we know from theory about deep inelastic processes and, as such, can be used for the comparison at higher energies including the LHC energies. From a good description of the experimental data, which is not better than in insufficient models of Refs.[14–33] we can conclude that the CGC/saturation approach does not contradict available experimental data. The weak statement is nevertheless stronger than the one that we can make from the models of Refs. [14–33]: shadowing corrections are, perhaps, needed to describe the experimental data. Formulating the result of the paper in one sentence, we firmly believe that only our model is reliable for extrapolation to higher energy including the LHC one.

We need to discuss why we use a model while, at first sight, we have a good description of the experimental data at least for the deep inelastic scattering, based on the leading order(LO) or even beyond of the leading order (NLO) perturbative QCD evolution equations (see Refs.[50–52]). Unfortunately, these equations as we have discussed, cannot provide reliable predictions for physical observables including F_2 , while the problem of large impact parameter behaviour of the scattering amplitude would not be solved theoretically and the CGC/saturation equations would have to be modified to include this behaviour. The solutions of the CGC/saturation equations that have been discussed, are valid only “under the approximation that the dipole scattering amplitude is independent on the impact parameter” (citation from Ref.[52]). Such an approximation generates the dipole scattering amplitude $N \propto \delta^{(2)}(Q_T)$ and $F_2 \propto \text{Im}N(Q_T = 0) \rightarrow \infty$, the prediction which cannot be compared with the experimental data. Therefore, we are doomed to build models for comparing with the experimental data. Using the results of these models we can evaluate how essential

is the b -dependence for the description of the experimental data, and see that it is essential even in the HERA kinematic region, and will be even more important at higher energy (i.e. at the LHC).

The second question is why we improve the model based on the leading order perturbative QCD while we know that the next-to-leading QCD corrections (NLO) are essential. The answer is: first we need to build a reliable model in the leading order QCD and only after this we can build the model that takes into account the NLO corrections. We believe that the NLO corrections will change all parameters of the model especially the energy behaviour of the saturation scale leading to small values of λ as it was demonstrated in Refs.[41, 49, 50]. Since the value of λ can be found from the solution of the linear equation we trust these estimates and, as we have discussed, we see in this NLO result the support for the phenomenological value of λ . However, we believe that we do not have enough solid theory information to discuss in the NLO the change in the behaviour of the scattering amplitude inside the saturation region building a model that includes the impact parameter behaviour. The general form of the non-linear equation in the NLO[53] shows that we can use the approach of Ref.[38] for finding an equation at $z \gg 1$ which takes the form

$$\frac{\partial N(Y; x, y)}{\partial Y} = -\bar{\alpha}_S \int d^2 z \left\{ K^{LO}(x, y|z) + \bar{\alpha}_S K^{NLO}(x, y|z) \right\} N(Y; x, y) \quad (5.1)$$

K^{NLO} turns out to be such that $K^{LO}(x, y|z) + \bar{\alpha}_S K^{NLO}(x, y|z) \rightarrow 0$ for $\bar{\alpha}_S z \sim 1$ [44, 49, 50]. It means that we cannot specify large z asymptotic behaviour using the NLO kernel. We have to re-sum all orders of $(\bar{\alpha}_S z)^n$ but we do not know a theory proof of the form of the non-linear equation for such a re-summed kernel. All attempts to write the non-linear evolution equation for the re-summed kernel (e.g. Refs.[49, 50]) use the simplified form of the kernel for the BFKL equation taking into account only its leading twist contribution. The correct coefficient from the full BFKL kernel in front of z^2 term in the solution at large $z \gg 1$, is much more important for phenomenology than the NLO corrections. Recalling that the running QCD coupling that should be included in such a re-summation, leads to the violation of the geometric scaling behaviour[54], and that the improved double log approximation of Ref.[50] cannot be used in the saturation region[38, 44, 49], we see that a lot of theory work must be done before we will be able to build a model that will include the impact parameter behaviour and the NLO corrections to the BK equation. We plan building such model as a natural goal for future work.

6 Acknowledgements

We thank our colleagues at Tel Aviv university and UTFSM for encouraging discussions. Our special thanks go to Asher Gotsman, Alex Kovner and Misha Lublinsky for elucidating discussions on the subject of this paper. This research was supported by the BSF grant 2012124, by the Fondecyt (Chile) grants 1130549 and 1140842 and by DGIP/USM grant 11.15.41.
